1. Introduction

Natural Forces has undertaken a shadow flicker impact assessment for the proposed Burchill Wind Project to assess the potential impact of shadow flicker on the surrounding shadow receptors. Details outlining the shadow receptors, prediction methodology, and model assumptions made for the assessment are included here, with the detailed windPRO software results included in Appendix B and Appendix C. This report also provides background information on the shadow flicker effect.

Under the *Additional Information Requirements for Wind Turbines* document published by the New Brunswick Ministry of Environment and Local Government pursuant to Section 5(2) of the *Environmental Impact Assessment Regulation of the Clean Environment Act*, requirements for visual impacts due to shadow flicker must be limited to 30 hours per year for a maximum of 30 minutes per day based on a “worst case” calculation where mitigation is not feasible. The worst case calculation is defined in the requirements document as the maximum shadow between sunrise and sunset on a cloudless day. These conditions have been adopted for this study, along with more realistic conditions for comparison.

Prior to determining the predicted amount of shadow flicker effect of a project, careful site design is recommended, followed by industry accepted mitigation strategies. This assessment will be used as supporting documentation to demonstrate that shadow flicker is being assessed and that compliance can be reached with careful planning and mitigation.

This shadow flicker analysis was conducted using the Shadow module of the software package, windPRO version 3.1.

1.1. Background

Flicker is caused by incident light rays on a moving object which then casts an intermittent shadow on a receptor. This intermittent shadow, perceived as a change in light intensity by an observer, as it pertains to a wind turbine generator (WTG), is referred to as shadow flicker. Shadow flicker is caused by incident sun rays on the rotor blades as they turn.

For shadow flicker to occur, the following criteria must be met:

1. The sun must be shining and not obscured by any cloud cover or fog.
2. The wind turbine must be between the sun and the shadow receptor.
3. The line of sight between the turbine and the shadow receptor must be clear. Light-impermeable obstacles, such as vegetation, buildings, awnings etc., will prevent shadow flicker from occurring at the receptor.
4. The shadow receptor must be close enough to the turbine to be in the shadow of the rotor.

1.2. Policy and Guidelines

In New Brunswick, there are provincial requirements for the acceptable amount of shadow flicker that can be experienced at a receptor. These requirements are set out in the *Additional Information Requirements for Wind Turbines* document published by New Brunswick Ministry of Environment and Local Government pursuant to Section 5(2) of the *Environmental Impact Assessment Regulation of the Clean Environment Act*.

Under these requirements, mitigation measures should be applied to minimize the shadow flicker effect on sensitive receptors. These mitigation measures can include relocation of turbines, screening of the receptors, and operational controls. Where the proponent demonstrates that the mitigation of any shadow flicker effect on sensitive receptors is not feasible, the amount of shadow flicker must be limited to:

- 30 hours per year for a maximum “worst case” calculation; and
- 30 minutes per day for a maximum “worst case” calculation.

The requirements also state that the “worst case” scenario describes a model that considers maximum shadow between sunrise and sunset and assumes cloudless skies throughout the year.

1.3. Source of Shadow

The proposed Burchill Wind Project is composed of 10 WTGs located roughly 15 kilometres southwest of the City of Saint John. A map of the project area with the proposed WTG layout is included in Appendix A.

There are no existing or proposed wind farms within 10 km of the proposed Burchill Wind Project; therefore, it is unlikely any cumulative WTG shadow flicker effects will occur external to the project.

The model of WTG being considered for the proposed wind project is the Enercon E-141 EP4, 4.2 MW machine. The E-141 turbines have a 141 m rotor diameter with a hub height of 135 m. This turbine model uses a horizontal axis, upwind, three blades, and a microprocessor pitch control system. Table 1 below outlines the main characteristics of this WTG model.

Table 1: Enercon E-141, 4.2 MW turbine characteristics.

Generator Type	Rotor Diameter (m)	Hub Height (m)	Swept area (m ²)	Rated Output (MW)
E-141 EP4	141	135	15,615	4.2

1.4. Receptors

There are 510 points of reception taken into consideration for this shadow flicker assessment. The receptors are mostly residential buildings, industrial buildings, and a few local businesses within 4 km of the proposed WTGs. They have been identified based on online geographical data from the Data Catalogue available on the Service New Brunswick website and cross referenced with aerial photography, as well as site visits. The geographic coordinates of the receptors are included in Appendix B. A map of the project area with the receptors is included in Appendix A.

2. Shadow Flicker Impact Assessment Methodology

The shadow flicker impact was calculated for the 10-turbine layout at each of the 510 receptors using the Shadow module of the software package windPRO version 3.1. This was carried out using different methodologies for the worst case and realistic scenarios, detailed below, to calculate the expected hours per year and maximum minutes per day of shadow flicker from the project for each receptor.

2.1. Worst Case Shadow Flicker Assessment

The worst case shadow flicker assessment follows a conservative methodology by modelling the Earth's orbit and rotation to provide the astronomical maximum shadow. The astronomical maximum shadow calculation assumes that for every day of the year:

1. The sky is cloudless between sunrise and sunset;
2. The turbines are always in operation; and,
3. The wind direction changes throughout the day such that the rotor plane is perpendicular to the incident sun rays at all times causing the maximum amount of shadow.

The position of the sun relative to the wind turbine rotor plane and the resulting shadow is calculated in steps of one-minute intervals throughout a complete year. If the rotor plane, assumed to be a solid disk equivalent in size to the swept area shown in Table 1 casts a shadow on a receptor window during one of these intervals, it is registered as one minute of potential shadow impact.

The impact of shadow flicker on surrounding receptors is limited by two factors in this worst case scenario. The first factor is that the angle of the sun over the horizon must be greater than 3 degrees, due to optic conditions in the atmosphere that cause the shadow to dissipate before it could potentially reach a receptor. The second factor is that the blade of the wind turbine must cover at least 20% of the incident solar rays in order to have a noticeable effect.

To further ensure the worst case scenario is being modelled, each receptor is treated as a greenhouse with 3.0 m high by 3.0 m wide windows for 360° of the building. Furthermore, no topographical or ground cover shielding caused by buildings, barns, trees, awnings, etc. has been considered between the wind turbines and receptors. This worst-case assumption results in a conservative prediction of the potential shadow flicker impacts, meaning that the shadow flicker impacts from the assessment are likely calculated as higher than they would be experienced.

2.2. Realistic Case Shadow Flicker Assessment

The realistic case shadow flicker assessment provides a model much closer to the actual conditions of the project site and the surrounding receptors. In this case, the Shadow module was used with the 'Real case based on statistics' option, which incorporates WTG operational hours and monthly sunshine probabilities into the model.

The input value for WTG operational hours was determined based on the average operational hours of all Natural Forces' existing operational turbines. On average, our turbines are operational, meaning that they are spinning, 95.17% of the time, which amounts to approximately 8,337 hours/year. Note that this does not take into account site-specific wind direction and therefore still remains a conservative model.

The monthly sunshine probabilities were input as the average daily hours of sunlight – the number of daylight hours during which sunny conditions are experienced. The input values for each month are listed in Table 2. Values were manually input because the nearest weather station in windPRO with sunlight data is Fredericton, NB, which is approximately 80 km from the site and experiences longer sunlight hours than Saint John.

Table 2: Average daily sunlight hours for Saint John, NB.¹

Month	Average Daily Sunlight Hours
January	3.42
February	4.35
March	4.90
April	5.30
May	6.50
June	6.67
July	7.22
August	6.67
September	5.53
October	4.80
November	3.13
December	3.22

The two receptors that were shown in the worst case scenario to experience shadow flicker levels exceeding the requirements were also modelled more realistically. Rather than treating each receptor as a greenhouse, the window height, width, and orientation (measured as degrees from south) were input based on data collected during a site visit. The inputs for all windows for these buildings facing the project are included below in Table 3.

Table 3: windPRO inputs for windows on the two buildings most impacted by shadow flicker.

Receptor	Window Description	Window Height Above Ground (m)	Window Height (m)	Window Width (m)	Window Orientation (degrees from south)
A: Simpson Truck and Tractor Parts	Long side of building, lower windows	1.0	1.0	3.0	12

H: GFL Environmental	Short side of building, upper warehouse windows	5.5	1.0	1.0	122

3. Results of Shadow Flicker Impact Assessment

The results of the shadow flicker prediction model at each receptor are used to demonstrate compliance with the New Brunswick requirements of no more than 30 hours per year of shadow, and no more than 30 minutes on the worst day of shadow under a realistic scenario.

The worst-case study of this project demonstrates that all but two of the receptors located within 4 km of the 10 WTG project layout are subject to no more than 30 hr/year and 30 min/day of shadow flicker. The detailed results of the shadow assessment study for all receptors in a worst case scenario are included in Appendix B.

The results show that of 510 receptors, 92 are predicted to experience shadow flicker under worst-case scenario conditions. Table 3 shows the results for the receptors that are predicted to experience 21+ hr/year of shadow flicker.

Table 3: Predicted worst case shadow flicker for E-141 at 135 m hub height for receptors predicted to experience 21+ hr/year of shadow flicker.

The receptors exceeding the requirements are two buildings in the Spruce Lake Industrial Park. These buildings are owned by Simpson Truck & Tractor Parts (receptor E) and GFL Environmental (receptor F). The GFL Environment building is a warehouse-style building with very few, small windows. The Simpson Truck & Tractor Parts building is an office/warehouse style building with narrow horizontal windows. Photos of these buildings are included in Figure 1 and Figure 2.

Figure 1: The Simpson Truck and Tractor Parts building (receptor E).

Figure 2: The GFL Environmental building (receptor F).

The realistic study, which considers the size of the windows for these two buildings, demonstrates that neither building is expected to experience shadow flicker exceeding 30 hr/year. The detailed results of this realistic case shadow flicker assessment for these two buildings is included in Appendix C and are summarized in Table 4. These results demonstrate that under realistic atmospheric and site conditions, neither of these two industrial buildings are predicted to experience shadow flicker that exceeds the requirements.

Though these realistic results do satisfy the provincial requirements, there are certain mitigation measures that can be implemented if needed, which are explored in Section 4.

Table 4: Predicted realistic case shadow flicker for E-141 WTGs with 135 m hub height for receptors predicted to have the most impact based on a worst case scenario.

Receptor	Window Description	Realistic Case Shadow Hours per Year (hr/year)
A: Simpson Truck and Tractor Parts	Long side of building, lower windows	12:15
B: GFL Environmental	Long side of building, upper warehouse windows	27:29
C: Simpson Truck and Tractor Parts	Long side of building, upper windows	9:37
D: Simpson Truck and Tractor Parts	Short side of building, lower window	7:07
E: Simpson Truck and Tractor Parts	Short side of building, upper window	6:15
F: GFL Environmental	Long side of building, lower windows	19:52
G: GFL Environmental	Short side of building, lower windows	12:42
H: GFL Environmental	Short side of building, upper warehouse windows	6:37

4. Proposed Mitigation

As required in the *Additional Information Requirements for Wind Turbines* report for New Brunswick, this shadow flicker assessment report also provides a description of the mitigation measures to be used to mitigate effects on sensitive receptors should they experience shadow flicker. These measures described in the following sections include tracking the events and screening of receptors using vegetation and awnings.

4.1. Tracking the Shadow Flicker

Should receptors experience shadow flicker and formalize a complaint, the complaint will be addressed following the Complaint Resolution Plan. The steps included in the Complaint Resolution Plan describe the study that will occur following a complaint. To begin, the specific date, time, and local weather conditions will be noted for each incident of shadow flicker as well as the duration of the event. Following this step, the Operation Team for the project will determine the direction of the wind relative to the receptor and the wind speed during the event. Finally, the details of the event will be tracked to analyze the specific conditions that cause shadow flicker at a receptor.

If the conditions causing shadow flicker are reoccurring and causing issues at the receptor, screening using vegetation and awnings may be considered to mitigate the situation.

4.2. Screening

Screening efforts are a feasible and effective mitigation measure for reducing shadow flicker impact. It is proposed that if receptors experience an annoyingly high amount of shadow flicker impact during operation, the Proponent could use screening methods that will provide shade to buildings and windows, effectively reducing shadow flicker annoyance.

Screening can be accomplished with existing vegetation, revegetation, and planting additional vegetation to the area which is experiencing shadow flicker. Similar, and sometimes better, results can be obtained by installing awnings and window if it would be preferred by those experiencing the impact.

5. Discussion and Conclusions

Natural Forces has completed an assessment to evaluate the shadow flicker impact of the proposed Burchill Wind Project at receptor locations within 4 km of the proposed WTGs.

Based on the worst case modelled results, the amount of shadow flicker predicted at each receptor, aside from two industrial buildings, will pass the requirements set out by New Brunswick's Ministry of Environment and Local Government. Based on the realistic modelled results, these two industrial buildings also will pass the requirements.

As per the *Additional Information Requirements for Wind Turbines* document published by New Brunswick Ministry of Environment and Local Government pursuant to Section 5(2) of the *Environmental Impact Assessment Regulation of the Clean Environment Act*, various measures may be used to mitigate effect of shadow flicker perceived at receptors. These mitigation methods may include tracking shadow flicker events and screening of receptors using natural barriers, awnings, or other structures.

The Proponent feels confident that receptors will not receive exceeding amounts of shadow flicker as demonstrated in the modelled worst-case and realistic scenarios. However, the Proponent will work closely with land and businesses owners to observe occurrences of real-case shadow flicker impact during operation and apply mitigation as mentioned.

SHADOW - Main Result

Calculation: Shadow: Worst Case - Burchill 10Tc - E-141 (4.2 MW, 135 m HH)

Assumptions for shadow calculations

Maximum distance for influence

Calculate only when more than 20 % of sun is covered by the blade

Please look in WTG table

Minimum sun height over horizon for influence

3

Minimum sail height over
Day stem for calculation

Time step for calculation

Time step for calculation

The calculated times are "worst case" given by the following assumptions:
The sun is shining all the day, from sunrise to sunset.

The sun is shining all the day, from sunrise to sunset.
The raster plane is always perpendicular to the line from

The rotor plane is always perpendicular to the line from the WTG to the sun
The WTG is always operating

The WIG is always operating

A ZVI (Zones of Visual Influence) calculation is performed before flicker calculation so non visible WTG do not contribute to calculated flicker values. A WTG will be visible if it is visible from any part of the receiver window. The ZVI calculation is based on the following assumptions:

Height contours used: Height Contours: CONTOURLINE_Birchill August 2018_19.wpo

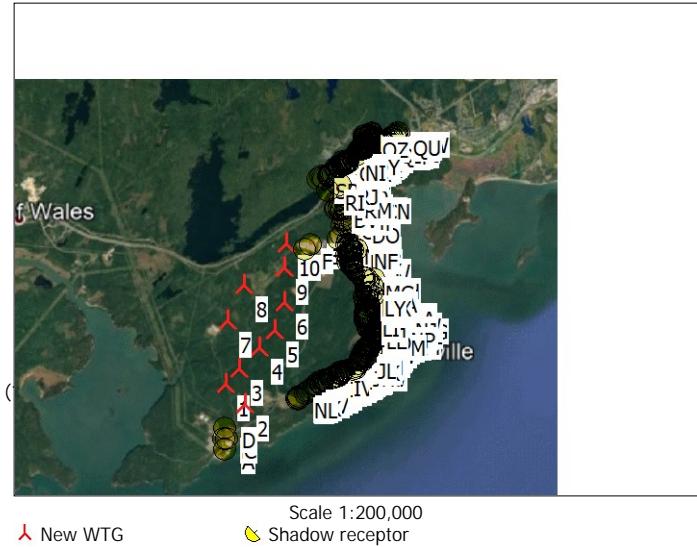

Obstacles used in calculation

Eye height: 1.5 m

Grid resolution: 10.0 m

Total times in Receptor wise and WTG wise tables can differ, as a WTG can lead to flicker at 2 or more receptors simultaneously and/or receptors may receive flicker from 2 or more WTGs simultaneously.

APPENDIX C:

WindPRO v3.1, Shadow Module Calculation Results
Worst Case

SHADOW - Main Result

Calculation: Shadow: Realistic Case - Burchill 10Tc - E-141 (4.2 MW, 135 m HH)

Assumptions for shadow calculations

Maximum distance for influence

Calculate only when more than 20 % of sun is covered by the blade

Please look in WTG table

Minimum sun height over horizon for influence

3 °

Day step for calculation

1 days

Time step for calculation

1 minutes

Sunshine probability S (Average daily sunshine hours) []

Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
3.42	4.35	4.90	5.30	6.50	6.67	7.22	6.67	5.53	4.80	3.13	3.22

Operational time

0 Sum

8,337 8,337

Idle start wind speed: Cut in wind speed from power curve

A ZVI (Zones of Visual Influence) calculation is performed before flicker calculation so non visible WTG do not contribute to calculated flicker values. A WTG will be visible if it is visible from any part of the receiver window. The ZVI calculation is based on the following assumptions:

Height contours used: Height Contours: CONTOURLINE_Birchill August 2018_19.wpo (1)

Obstacles used in calculation

Eye height: 1.5 m

Grid resolution: 10.0 m

All coordinates are in

UTM (north)-NAD83 (US+CA) Zone: 19
